

FINANCIAL SERVICES ADVISORY

Climate risk quantification

How Grant Thornton can help to quantify
and manage your climate risk

Overview

The global economic crisis that resulted as a consequence of the pandemic has stressed the relevance of prioritising sustainability pillars within financial services.

In addition, it is becoming increasingly clear that such risks are being realised and can be measured, monitored, and mitigated. This has driven the global regulatory community to seek ways in codifying ESG risks, especially those that are climate change-related, into a single risk type.

Of course, risk is inversely linked to opportunity and the emergence of such additional risks presents potential areas of growth and competitive advantage for banks in recognising such pathways more efficiently than their competitors.

Grant Thornton's ESG services are across three pillars, Strategy, Risk Management and Integration. This document outlines our focus on the development of a climate change risk quantification, stress testing, and portfolio management framework. This framework aims to identify and measure key vulnerabilities in a bank's portfolios given the negative effects of climate change, as well as to identify opportunities for growth in reference to risk based pricing reflective of climate risks.

Our services

Grant Thornton provides a full suite of Environmental, Social and Governance (ESG) advisory services for Financial Services institutions across:

Grant Thornton's dedicated financial services advisory teams across Consulting, Risk and Advisory can deliver across each of these key areas. This document focuses on Risk Management. Details of our Strategy and Integration services are also available.

ESG pillars

Environmental:

- climate change strategy;
- biodiversity;
- resource depletion;
- air and water pollution;
- Deforestation;
- water efficiency;
- energy efficiency;
- carbon intensity;
- environmental;
- management system.

Social:

- diversity and equal opportunities;
- human rights;
- employee training/upskilling;
- freedom of association;
- health and safety;
- human rights;
- customer and products responsibility;
- child labour;
- local and indigenous communities.

Governance:

- business ethics;
- compliance;
- board independence, diversity and structure;
- executive compensation;
- shareholder democracy;
- bribery and corruption;
- tax strategy;
- transparency;
- shareholder rights.

Climate risk and regulations

Institutions are expected to:

- include climate-related and environmental risks in all stages of credit-granting process and credit processing (impact on PD);
- adjust risk classification procedures in order to identify and evaluate climate-related and environmental risks (impact on PD);
- consider climate-related and environmental risks in collateral valuations (impact on LGD);
- monitor and manage credit risks in their portfolios, through sectoral/geographic/single-name concentration analysis, including credit risk concentrations stemming from climate-related and environmental risks (impact on Economic Capital, RWA, and ECL provisions);
- reflect credit risk appetite and business strategy in their loan pricing frameworks with regards to climate-related and environmental risks (impact on ICAAP, ILAAP, SREP); and
- reflect the different costs in their loan pricing driven by climate-related and environmental risks (impact on RAROC).

Climate risk stress test

ECB's climate stress test methodology is indicative, with no direct implications linked to the bank's capital requirements.

The results of this stress test exercise will provide the regulator with insights into the bank's climate risk exposures, which might affect the Pillar 2 requirements via the Supervisory Review and Evaluation Process (SREP) scores.

Module one: Questionnaire

78 questions in categories:

- climate risk stress test governance and risk appetite;
- integration of climate risk stress test into institution's strategy;
- stress test methodology and scenarios;
- data;
- ICAAP;
- future plans regarding climate stress testing and other priorities;
- internal audit function;
- assumptions for climate.

Source | Gather | Interpret

Module two: Benchmarking

- Comparison of banks across a common set of climate risk metrics.
- Measurement of the banks' dependency income on carbon-intensive industries.
- Banks should split their portfolio into 22 NACE / SIC codes based industry activities.

Identify | Define | Quantify

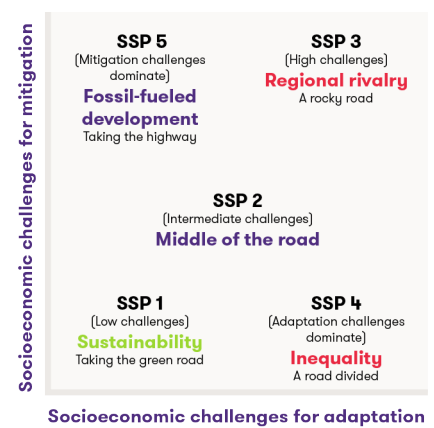

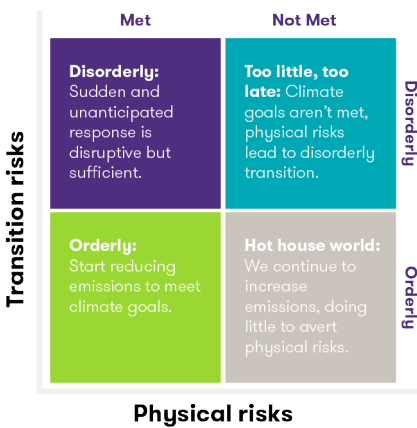

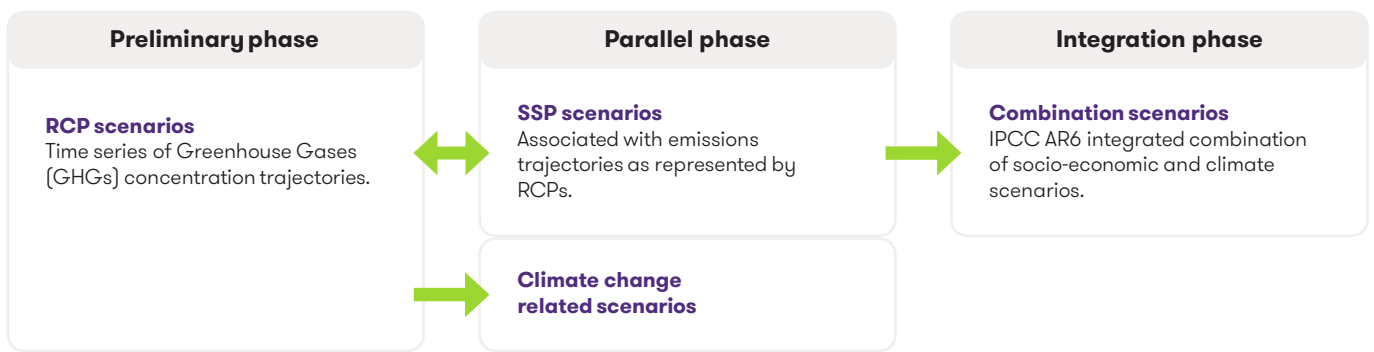

Module three: Stress test

- Targeting transition and physical risks.
- Assessment of the impact of extreme weather conditions.
- Estimating the potential increase in the price of carbon emissions and banks' response to the transition scenarios over a 30-year horizon.
- Consideration of the impact on credit risk via transition risk.

Develop | Enhance | Implement

Climate scenario design

Leveraging globally accepted solutions

Network for greening the financial system

Provide framework for analysing climate risks, identifying key transition and physical risks associated with climate change.

Physical risk: Impact from increasing frequency and magnitude of natural hazards.

Transition risk: Financial loss from the process of adjustments towards a sustainable economy.

Framework allows examination of the economic impact of policies implemented in representative scenarios - namely:

Orderly: Effective policies implemented early.

Disorderly: Policy implantation delayed before abrupt and costly action taken.

Hot house world: Little further action is taken. Limited transition risk but high physical risk.

The Representative Concentration Pathways (RCPs)

RCPs are designed for modelling different climate futures depending on GHG emissions. These give estimates for emissions trajectory based on various assumptions specific to each pathway.

Each RCP pathway defines a specific radiative forcing by 2100 - RCP8.5 implies global warming of 8.5 Wm⁻² by 2100.

Shared Socioeconomic Pathways (SSPs) framework

The SSPs framework contains alternate socioeconomic scenarios developed to aid in assessing future risks due to the changing socio-economic landscape. The scenarios are:

- Sustainability;
- Middle of the road;
- Regional rivalry;
- Inequality;
- Fossil fueled development.

Scenario construction:

RCP scenarios: Emission trajectories are used as inputs for climate models.

SSP scenarios: Socio-economic narratives are translated into GHG emission trajectories.

NGFS scenarios: Identification of physical and transition risks under different climate futures.

IPCC Assessment Report (AR6): A new 'parallel' process is established for the construction of integrated RCP-SSP combination scenarios.

Risk quantification

Bottom-up approach

Adoption of borrower specific climate risk drivers as part of grading e.g. impact based on geolocation and sector

Incorporation of ESG drivers in loan pricing for individual borrowers RAROC-based

Translation of climate risk drivers into a credit risk profile on a borrower level Scorecard

Translation of macro-economic shocks into bank risk measures Stress testing

Scorecards:

Borrower specific ESG risk drivers and metrics available by external agencies, borrower specific financial factors driven by climate change risks.

Stress testing:

Climate model scenarios, socio-economic scenarios, emissions and radiative forcing scenarios

Limitations:

Data granularity not readily available, limited historical data availability, system set-up requirement for data collection.

Top-down approach

Use of regression models to estimate the relationship between climate risk drivers, economic variables, and bank risk measures

Stress-testing on portfolio, sub-portfolio, or sector level

Translation of climate risk drivers into a credit risk profile measuring the systematic element of the risk

Translation of macro-economic shocks into bank risk measures

Data requirements:

Bank default rates and macro-economic variables, climate and physical drivers, transition and policy drivers, socio-economic indicators, emission and radiative forcing indicators.

Limitations:

Impact of climate change and environmental risks not available on borrower level.

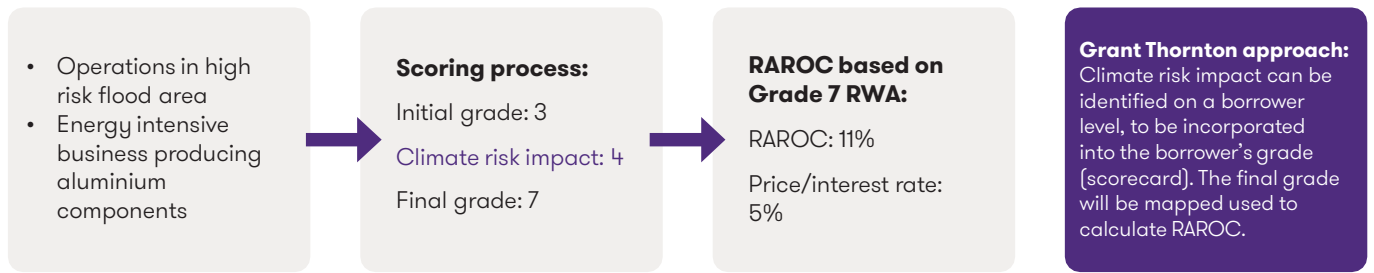

Heat map that identifies the potential impact of sustainability across the sectors, asset classes and lending activities¹.

	Consumer goods	Extractives & mineral processing	Financials	Food & beverage	Healthcare	Infrastructure	Renewable resources & alternative energy	Resource transformation	Services

Social capital									
Human capital									
Business model & innovation									
Leadership & governance									

Methodology overview

Bottom-up

Top-down

Seemingly Unrelated Regression (SUR) model

SUR models identify sector-specific dynamics, considering that climate risks have differing impacts across sectors and geographic locations.

Inter-correlation (correlations between sectors) is factored-in via the correlation of residuals of sector-specific equations which capture systematic risk driven by interdependencies of sectors

The SUR model structure is as follows:

$$y_{ti} = \sum_{j=1}^n \beta_{ij} X_{tij} + \varepsilon_{ij}$$

y_{ti} : A vector of computed bank risk measures e.g., defaults rates, for i individual sectors.

X_{tij} : A sector-specific explanatory variable j , appearing in the i^{th} sectoral equation.

ε_{ij} : Error term.

Contact

Our team would be delighted to discuss your challenges and opportunities in any aspect of climate risk. Our services are flexible and efficient, designed to facilitate and support your business model. Contact us today to discuss.
